Processing

Internally lifecycle can get quite complex. It can span several organizations (interoperability). How about insight? Can we open lifecycle and build open data by design?

Open data lifecycle (II)

- Data collections can consist of **large amount of information** and there can be a need of tracking data changes or lifecycle procedures through a long period of time (in order to **track historical changes**).
- Also, the case study shows that the (pollution) data can be **very sensitive**, so collection and processing should be verified and there should be **a clear data handling methodology** to ensure important quality issues.
- Important quality issues regarding open data systems (disclaimers are not good for development of open data market):
 - **quality of the data** itself, like reliability, consistency and usefulness and
 - **quality of the data handling procedures**.
- Some important quality issues of data handling procedures are **transparency** and the ability to **verify** that the data is processed from its source to the end-user in a way that maintains reliability and correctness.

Open data lifecycle (III)

- In order to achieve **transparency** and establish the ability to **verify** the handling of the data from its source to the end-user in an appropriate way, we suggest the use of **the Business Process paradigm** to represent the lifecycle of the open data.
- The openness and transparency of the consistent process model of handling open data (the lifecycle of open data) enables re-user's trust in data quality and persistence.
- Also **the cost per unit of data** can be calculated and simulated in advance (utilization of graph theory and colored Petri nets)

Process paradigm

- process analysis
- process modelling
- process execution by utilizing information technologies
- important for development, implementation and use of information systems in modern organizations

BPMN 2.0 - Business Process Model and Notation

<http://bpmb.de/poster>

Activities

- Task**: A Task is a unit of work, the job to be performed. When marked with a symbol it indicates a Sub-Process, an activity that can be refined.
- Transaction**: A Transaction is a set of activities that logically belong together; it might follow a specified transaction protocol.
- Event Sub-Process**: An Event Sub-Process is placed into a Process or Sub-Process. It is activated when its start event gets triggered and can interrupt the higher level process context or run in parallel (non-interrupting) depending on the start event.
- Call Activity**: A Call Activity is a wrapper for a globally defined Sub-Process or Task that is reused in the current process.

Activity Markers

- Sub-Process Marker
- Loop Marker
- Parallel All Marker
- Sequential All Marker
- Ad Hoc Marker
- Compensation Marker

Task Types

- Send Task
- Receive Task
- User Task
- Manual Task
- Business Rule Task
- Service Task
- Script Task

- Sequence Flow**: defines the execution order of activities.
- Default Flow**: is the default branch to be chosen if all other conditions evaluate to false.
- Conditional Flow**: has a condition assigned that defines whether or not the flow is used.

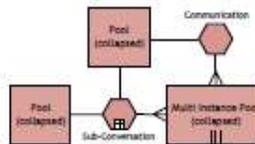

Gateways

- Exclusive Gateway**: When splitting, it routes the sequence flow to exactly one of the outgoing branches. When merging, it awaits one incoming branch to complete before triggering the outgoing flow.
- Event-based Gateway**: Is always followed by catching events or receive tasks. Sequence flow is routed to the subsequent event/task which happens first.
- Parallel Gateway**: When used to split the sequence flow, all outgoing branches are activated simultaneously. When merging parallel branches it waits for all incoming branches to complete before triggering the outgoing flow.
- Inclusive Gateway**: When splitting, one or more branches are activated. All active incoming branches must complete before merging.
- Exclusive Event-based Gateway**: Each occurrence of a subsequent event starts a new process instance.
- Complex Gateway**: Complex merging and branching behavior that is not captured by other gateways.
- Parallel Event-based Gateway (Instantiated)**: The occurrence of all subsequent events starts a new process instance.

Conversations

- A Communication defines a set of logically related message exchanges. When marked with a symbol it indicates a Sub-Conversation, a compound conversation element.
- A Conversation Link connects Communications and Participants.
- A Forked Conversation Link connects Communications and multiple Participants.

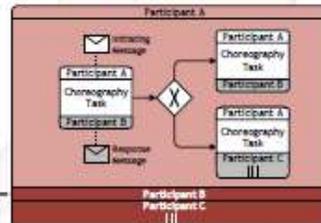

Conversation Diagram

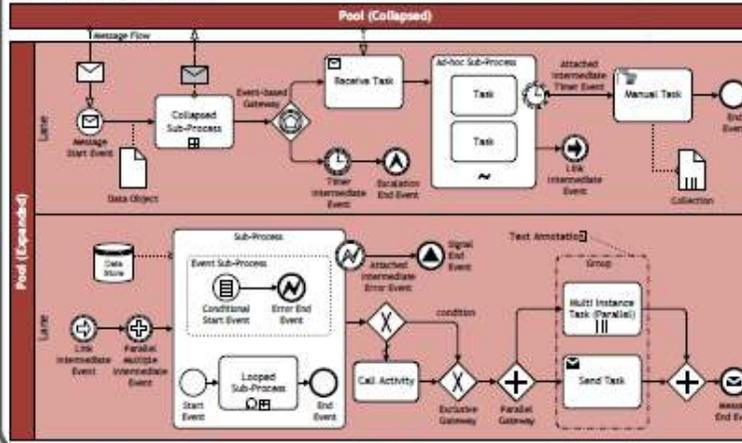

Choreographies

- A Choreography Task represents an Interaction (Message Exchange) between two Participants.
- Multiple Participants Marker denotes a set of Participants of the same kind.
- A Choreography Sub-Process contains a refined choreography with several interactions.

Choreography Diagram

Collaboration Diagram

Swimlanes

- Pools (Participants) and Lanes represent responsibilities for activities in a process. A pool or a lane can be an organization, a role, or a system. Lanes subdivide pools or other lanes hierarchically.
- Message Flow symbolizes information flow across organizational boundaries. Message flow can be attached to pools, activities, or message events.
- The order of message exchanges can be specified by combining message flow and sequence flow.

Events

	Start	Intermediate	End
None: Unrelated events			
Indicate start point, state changes or final states			
Message: Receiving and sending messages			
Timer: Cyclic timer events, points in time, time spans or timeouts			
Escalation: Escalating to an higher level of responsibility			
Conditional: Reacting to changed business conditions or integrating business rules			
Link: Off-page connectors. Two corresponding link events equal a sequence flow.			
Error: Catching or throwing named errors			
Cancel: Reacting to cancelled transactions or triggering cancellation			
Compensation: Handling or triggering compensation			
Signal: Signalling across different processes. A signal thrown can be caught multiple times			
Multiple: Catching one out of a set of events. Throwing all events defined			
Parallel Multiple: Catching all out of a set of parallel events			
Terminate: Triggering the immediate termination of a process			

Data

- A Data Input is an external input for the entire process. It can be read by an activity.
- A Data Output is a variable available as result of the entire process.
- A Data Object represents information flowing through the process, such as business documents, e-mails, or letters.
- A Collection Data Object represents a collection of information, e.g., a list of order items.
- A Data Store is a place where the process can read or write data, e.g., a database or a filing cabinet. It persists beyond the lifetime of the process instance.
- A Message is used to depict the contents of a communication between two Participants.

Koji je optimalni broj modula IS-a (podsustava, aplikacija)?

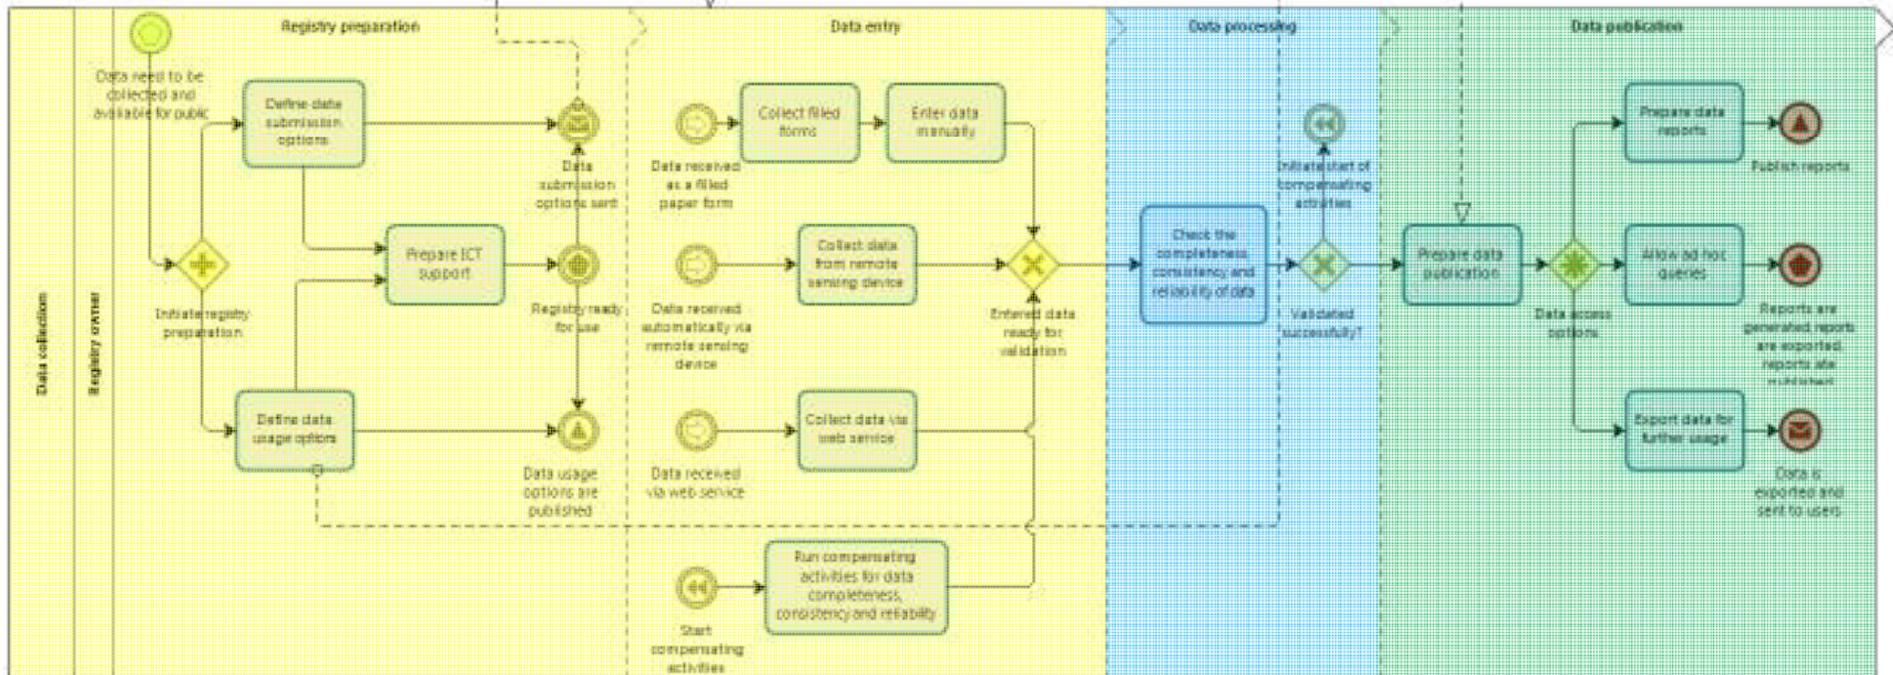

BPMN model of Environmental Pollution Register

Gathering

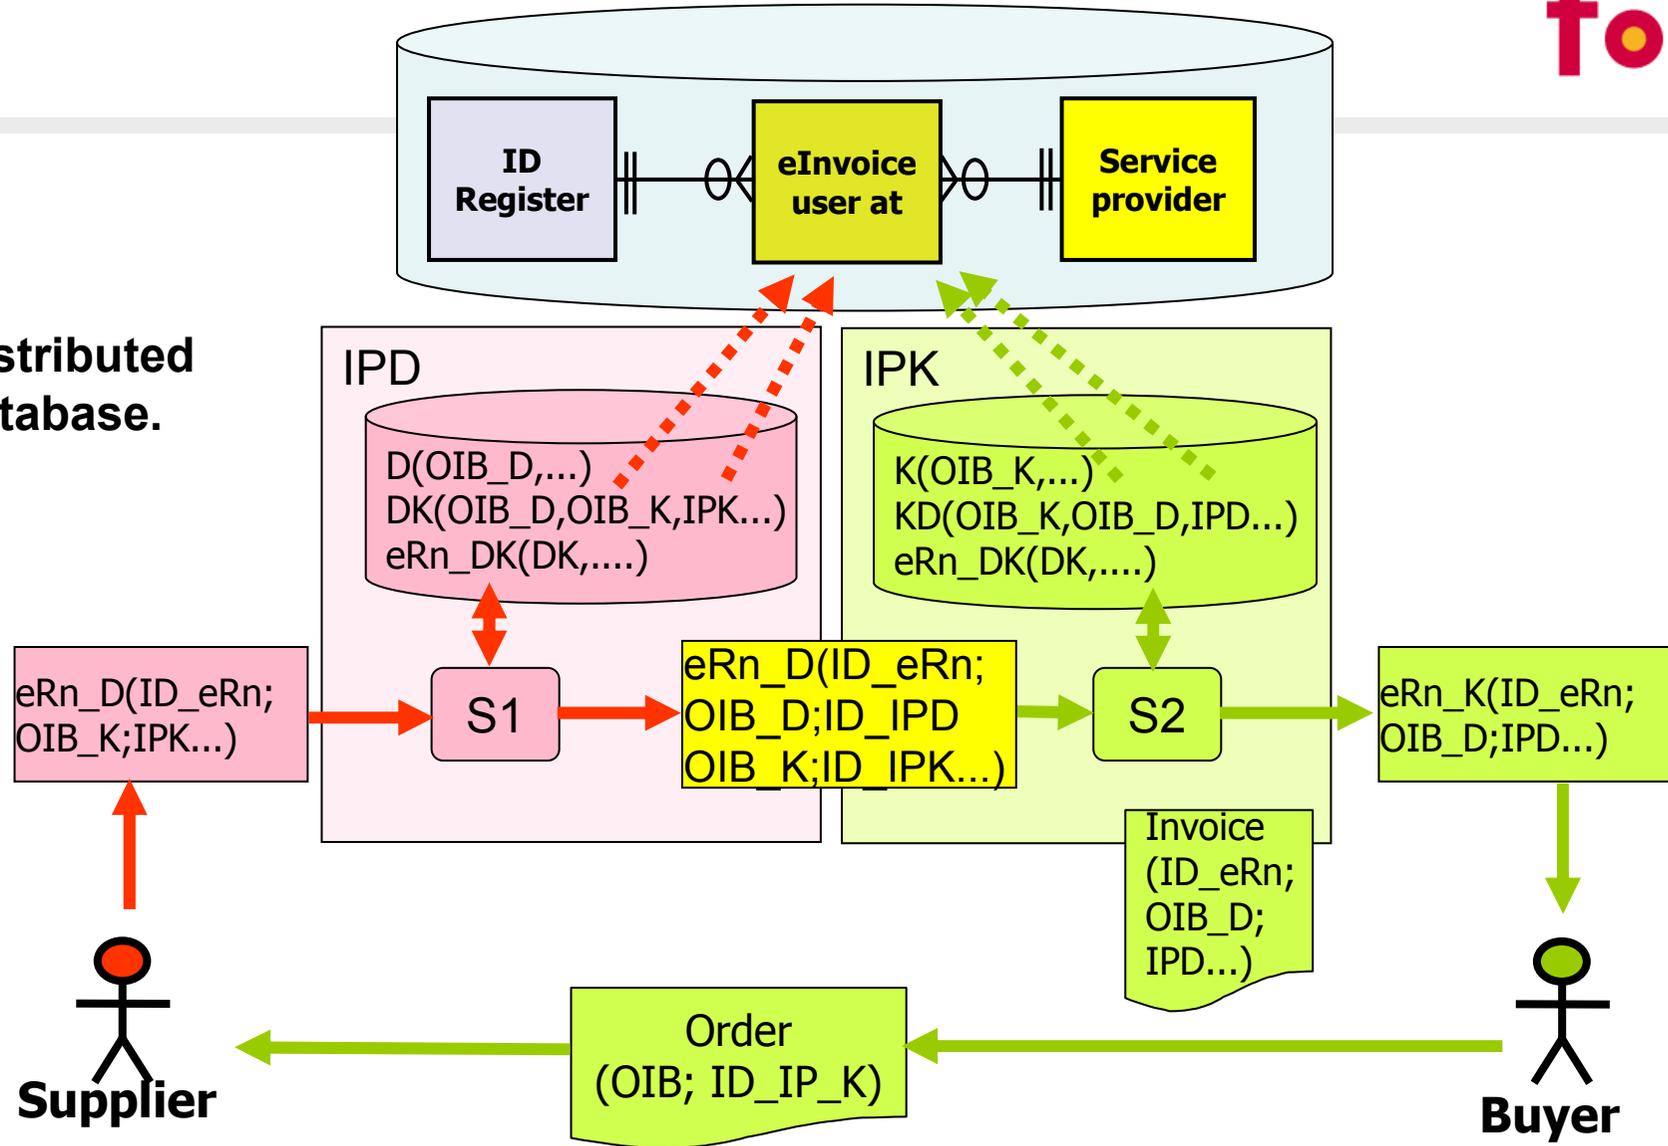

Delivering

Processing

Distributed database.

What we achieved?

- Analysys can be extended to desired level of detail
- Deep insight into business processes for all stakeholders
- Consistency of procedures
- Process simulation (what if analysis)
- Cost evaluation and monitoring

Challenges and benefits regarding data delivering

- It can be useful to mind that users can be external and internal. Internal re-users, like the public bodies themselves, often use the open data only for purposes of redistributing the same information to other external users (e.g. links to web pages)
 - Example of this kind of data consumption by public/governmental bodies themselves - ***Assessment of sea bathing water quality***. Based on this open data collection a National annual report on sea bathing water quality at Croatian beaches is published. Other governmental institutions use this data in their domain (Ministry of tourism, Local departments of public Health,...).
